

**Problem Set #4 Solutions**

Rosen, Section 1.8

#8

- a)  $O(x^4)$ :  $n=3$  is too small since  $\log x$  grows without bound as  $x$  increases. But it does grow smaller than  $x$  so  $n=4$  is the best answer.  
 b)  $n = 5$   
 c) For large  $x$ , this fraction gets close to 1 (divide numerator and denominator by  $x^4$ ). so  $n = 0$  and we get  $O(1)$ .  
 d) Similar to c, but this time  $n = -1$  since for large  $x$ ,  $f(x)$  is approximately  $= 1/x$ .

#32 Give a big-oh estimate of the product of the first  $n$  odd positive integers.

The  $n$ th odd positive integer  $= 2n-1$ . Thus each of the first  $n$  odd positive integers is at most  $2n$ . So their product is at most  $(2n)^n$  giving us  $O((2n)^n)$ .

We also accepted any other *legal* tighter bounds as answers.

#38 The definition of “ $f(x)$  is  $\Theta(g(x))$ ” is that  $f(x)$  is both  $O(g(x))$  and  $\Omega(g(x))$ . That means that there exists positive constants  $C_1, k_1, C_2, k_2$  such that  $|f(x)| \leq C_2 |g(x)|$  for all  $x > k_2$  and  $|f(x)| \geq C_1 |g(x)|$  for all  $x > k_1$ . Similarly, we have the positive constants  $C_1', k_1', C_2', k_2'$  such that  $|g(x)| \leq C_2' |h(x)|$  for all  $x > k_2'$  and  $|g(x)| \geq C_1' |h(x)|$  for all  $x > k_1'$ . We can combine these inequalities to obtain  $|f(x)| \leq C_2 C_2' |h(x)|$  for all  $x > \max(k_2, k_2')$ , and  $|f(x)| \geq C_1 C_1' |h(x)|$  for all  $x > \max(k_1, k_1')$ . This means that  $f(x)$  is  $\Theta(h(x))$ .

1) In pseudocode:

$i = m;$	1
$j = n;$	1
$\text{pair} = (0,0);$	1
repeat until $i = 0$ or $j = 0$ {	$m+n$ (worst case)
if $u_i + d_j = C$ then	$m+n$
$\text{pair} = (i, j);$	
exit;	
else if $u_i + d_j < C$ then	$m+n$
$j = j - 1;$	worst case: $m$ times
else if $u_i + d_j > C$ then	$m+n$
$i = i - 1;$	worst case: $n$ times

// Indices of the summands for  $C$  will be in “pair” or  $(0,0)$  if  $C$  is not obtainable.

Note: The conditions of the if-statement will execute each time through the loop, but only one set of statements inside will execute each time, with worst case being  $m+n$  (if  $C$  is not obtainable):  $5(m+n) + 3$ , which is  $O(m+n)$  and is linear.

$$2) n^3 + n^2(n+1) + n(n+1) + (n+1) = O(n^3)$$

3) Note that the value of  $\text{bar}(n,n) = (n^2 + 3n)/2$ . The function bar takes  $O(n)$  time and line (2) of foo takes  $O(n)$  time. The for-loop of lines (1)-(2) is iterated  $(n^2 + 3n)/2$ . The evaluation of  $\text{bar}(n,n)$  at line (1) takes  $O(n)$  time. Thus, the procedure foo now takes  $O(n^3)$  time (using the product rule). The running time of main is dominated by the running time of foo and thus main also takes  $O(n^3)$  time.

$$4) P(n): s_n = \begin{cases} 2^{((n+1)/2)} & \text{if } n \text{ is odd} \\ 2^{(n/2)} & \text{if } n \text{ is even} \end{cases}$$

proof by strong induction:

$$P(n) \text{ denotes that: } s_n = \begin{cases} 2^{((n+1)/2)} & \text{if } n \text{ is odd} \\ 2^{(n/2)} & \text{if } n \text{ is even} \end{cases}$$

i) base case: Prove  $P(0)$  and  $P(1)$  are true: if  $n = 0$ ,  $2^0 = 1$ ; if  $n = 1$ ,  $2^{(2/2)} = 2$

ii) induction: assume that the formula holds all positive integers  $i < k$ ; show that it holds for  $k$ .

$$s_i = \begin{cases} 2^{((i+1)/2)} & \text{if } i \text{ is odd} \\ 2^{(i/2)} & \text{if } i \text{ is even} \end{cases}$$

$$s_k = 2 * s_{k-2} \quad \text{given}$$

$$\begin{aligned} & 2 * 2^{(((k-2)+1)/2)} & \text{if } k-2 \text{ is odd} & \text{substitution of inductive hypothesis:} \\ & 2 * 2^{((k-2)/2)} & \text{if } k-2 \text{ is even} & \text{k-2 is less than k} \end{aligned}$$

$$\begin{aligned} & 2^{((k-1)/2 + 1)} & \text{if } k-2 \text{ is odd} & \text{definition of exponents \& algebra} \\ & 2^{((k-2)/2 + 1)} & \text{if } k-2 \text{ is even} \end{aligned}$$

$$\begin{aligned} & 2^{((k-1)/2 + 1)} & \text{if } k \text{ is odd} & \text{definition of odd/even; if } k \text{ is odd so is} \\ & 2^{((k-2)/2 + 1)} & \text{if } k \text{ is even} & \text{k-2; if } k \text{ is even so is k-2} \end{aligned}$$

$$\begin{aligned} & 2^{((k+1)/2)} & \text{if } k \text{ is odd} & \text{algebra} \\ & 2^{(k/2)} & \text{if } k \text{ is even} \end{aligned}$$

By the principle of strong mathematical induction,  $P(n)$  is true for all  $n \geq 0$ .

5) Discover and prove a formula for

$$\sum_{k=1}^n k^2$$

$$(2n^3 + 3n^2 + n) / 6 \quad \text{Taken from Handout \#9}$$

$P(n)$ : A closed form formula for the summation above is  $(2n^3 + 3n^2 + n) / 6$

base case:  $1^2 = (2 * 1 + 3 * 1 + 1) / 6 = 1$

inductive hypothesis: Assume  $P(n)$  is true, prove it is true for  $P(n+1)$ , i.e.,

$$\sum_{k=1}^{n+1} k^2 = (2(n+1)^3 + 3(n+1)^2 + (n+1)) / 6$$

Proof:

$$\sum_{k=1}^n k^2 + (n+1)^2 = (2n^3 + 3n^2 + n) / 6 + (n+1)^2$$

$$\begin{aligned} \sum_{k=1}^{n+1} k^2 &= (2n^3 + 3n^2 + n) / 6 + (n+1)^2 \\ &= (2n^3 + 3n^2 + n) / 6 + 6(n^2 + 2n + 1) / 6 \\ &= (2n^3 + 9n^2 + 13n + 6) / 6 \\ &= (2(n+1)^3 + 3(n+1)^2 + (n+1)) / 6 \end{aligned}$$

By the principle of mathematical induction,  $P(n)$  is true for  $n$ .

6)  $u_n = 1 + 3 + 3^3 + 3^4 + \dots + 3^n = (3^{(n+1)} - 1) / 2$  (geometric series)

7a) We assume that  $i > j$  in the following function:

```
int gcd(int i, int j) {
    int r;

    r = i % j;
    if (r != 0)
        gcd(j, r);
    else
        return j;
}
```

7b) Let  $T(i)$  be the running time of  $\text{gcd}(i, j)$ . Suppose  $\text{gcd}(i, j)$  calls  $\text{gcd}(j, m)$  which calls  $\text{gcd}(m, n)$ . We shall show that  $m \leq i/2$ . There are two cases:

- 1)  $j \leq i/2$  then  $m \leq j \leq i/2$ .
- 2)  $j > i/2$ , then  $m = i \% j = i - j < i/2$

Thus, we conclude that after every two calls to  $\text{gcd}$ , the first argument is reduced by at least half. If we substitute the text of  $\text{gcd}$  for one invocation of the recursive call, we can model the running time of  $\text{gcd}$  by the recurrence:

$$T(i) \leq O(1) + T(i/2)$$

The solution to this recurrence is  $O(\log i)$ .
